In the previous week, I showed you how we can plot word vectors. Now, you will see how you can take a word vector and learn a mapping that will allow you to translate words by learning a "transformation matrix". Here is a visualization:

Note that the word "chat" in french means cat. You can learn that by taking the vector corresponding to "cat" in english, multiplying it by a matrix that you learn and then you can use cosine similarity between the output and all the french vectors. You should see that the closest result is the vector which corresponds to "chat".

Here is a visualization of that showing you the aligned vectors:

$$\mathbf{X}\mathbf{R} \approx \mathbf{Y}$$

$$\begin{pmatrix} [\,\text{"cat" vector}\,] \\ [\,\ldots \text{vector}\,] \\ [\,\text{"zebra" vector}\,] \end{pmatrix} \qquad \begin{pmatrix} [\,\text{"chat" vecteur}\,] \\ [\,\ldots \text{vecteur}\,] \\ [\,\text{"zébresse" vecteur}\,] \end{pmatrix}$$

$$\mathbf{X} \qquad\qquad\qquad \mathbf{Y}$$

subsets of the full vocabulary

[handwritten margin notes in Persian/Farsi:]
* نکته: مملئہ سوال پیش بیاد كه چرا از یك map ساده استفاده نكنیم؟ dictionary
علتش اینه كه توى این رشته (nlp) با استفاده از یك زیرمجموعہ از كلمات همزبان با رسیدن به یك مدل دقیق بعراحتی بقیہ كلماتی كه در حجم learn انبودن را نیز می‌توان ترجمہ كرد.

Note that X corresponds to the matrix of english word vectors and Y corresponds to the matrix of french word vectors. R is the mapping matrix.

Steps required to learn R:

- Initialize R

- For loop

$Loss = \|XR - Y\|_F$

$g = \frac{d}{dR} Loss$

$R = R - \alpha * g$

Here is an example to show you how the frobenius norm works.

$\|\mathbf{X}\mathbf{R} - \mathbf{Y}\|_F$

$\mathbf{A} = \begin{pmatrix} 2 & 2 \\ 2 & 2 \end{pmatrix}$

$\|\mathbf{A}_F\| = \sqrt{2^2 + 2^2 + 2^2 + 2^2}$

$\|\mathbf{A}_F\| = 4$

$\|\mathbf{A}\|_F \equiv \sqrt{\sum_{i=1}^{m} \sum_{j=1}^{n} |a_{ij}|^2}$

In summary you are making use of the following:

- $\mathbf{X}\mathbf{R} \approx \mathbf{Y}$
- minimize $\|\mathbf{X}\mathbf{R} - \mathbf{Y}\|_F^2$

Imagine you had to cluster the following figures into different buckets:
Note that the figures blue, red, and gray ones would each be clustered with each other
You can think of hash function as a function that takes data of arbitrary sizes and maps it to a fixed value. The values returned are known as *hash values* or even *hashes* .

0	1	2	3	4	5	6	7	8	9
100				14			17		
10							97		

Hash function (vector) ⟶ Hash value

Hash value = vector % number of buckets

The diagram above shows a concrete example of a hash function which takes a vector and returns a value. Then you can mod that value by the number of buckets and put that number in its corresponding bucket. For example, 14 is in the 4th bucker, 17 & 97 are in the 7th bucket. Let's take a look at how you can do it using some code.

```python
def basic_hash_table(value_l,n_buckets):
    def hash_function(value_l,n_buckets):
        return int(value_l) % n_buckets
    hash_table = {i:[] for i in range(n_buckets)}
    for value in value_l:
        hash_value = hash_function(value,n_buckets)
        hash_table[hash_value].append(value)
    return hash_table
```
* نکته : هَش ساده ابرای دسته بندی کردن کلیت مشابه در هم
لک کنند. ه دست جون کلا توی مثال زده شده 94و 100 تَوی در دسته
جا قرار گرفت درحالِ که به نظر می رسید مشابه بهم باشی.

لَ حل داریم Locality hash table

Locality sensitive hashing is a technique that allows you to hash similar inputs into the same buckets with high probability.

"Planes"

Instead of the typical buckets we have been using, you can think of clustering the points by deciding whether they are above or below the line. Now as we go to higher dimensions (say n-dimensional vectors), you would be using planes instead of lines. Let's look at a concrete example:

$$V_2 = \begin{pmatrix} -1 & 1 \end{pmatrix}$$

$$P = \begin{pmatrix} 1 & 1 \end{pmatrix}$$

$$V_1 = \begin{pmatrix} 1 & 2 \end{pmatrix}$$

$$V_3 = \begin{pmatrix} -2 & -1 \end{pmatrix}$$

الضرب لبعضها P والاردي V₁

$$PV_1^T = 3$$

$$PV_2^T = 0$$

$$PV_3^T = -3$$

Notice the signs?

Given some point located at (1,1) and three vectors $V_1 = (1, 2), V_2 = (-1, 1), V_3 = (-2, -1)$ you will see what happens when we take the dot product. First note that the dashed line is our plane. The vector with point $P = (1, 1)$ is perpendicular to that line (plane). Now any vector above the dashed line that is multiplied by $(1, 1)$ would have a positive number. Any vector below the dashed line when dotted with $(1, 1)$ will have a negative number. Any vector on the dashed line multiplied by $(1, 1)$ will give you a dot product of 0.

Here is how to visualize a projection (i.e. a dot product between two vectors):

norm vector =nv

X

+

−

plane

$X \cdot nv \geqslant 0 \longrightarrow 1$

$X \cdot nv < 0 \longrightarrow -1$

```
num_dimensions = 2 #300 in assignment
num_planes = 3 #10 in assignment

random_planes_matrix = np.random.normal(
                        size=(num_planes,
                              num_dimensions))

array([[ 1.76405235  0.40015721]
       [ 0.97873798  2.2408932 ]
       [ 1.86755799 -0.97727788]])

v = np.array([[2,2]])
```
```
def side_of_plane_matrix(P,v):
    dotproduct = np.dot(P,v.T)
    sign_of_dot_product = np.sign(dotproduct)
    return sign_of_dot_product

num_planes_matrix = side_of_plane_matrix(
                        random_planes_matrix,v)

array([[1.]
       [1.]
       [1.])
```

$$\|PV_1^T\|$$

When you take the dot product of a vector V_1 and a P, then you take the magnitude or length of that vector, you get the black line (labelled as Projection). The sign indicates on which side of the plane the projection vector lies.

The previous video shows you a toy example of how you can actually represent a document as a vector.

```python
word_embedding = {"I": np.array([1,0,1]),
                  "love": np.array([-1,0,1]),
                  "learning": np.array([1,0,1])}

words_in_document = ['I', 'love', 'learning']

document_embedding = np.array([0,0,0])

for word in words_in_document:
    document_embedding += word_embedding.get(word,0)

print(document_embedding)
array([1 0 3])
```

In this example, you just add the word vectors of a document to get the document vector. So in summary you should now be familiar with the following concepts:

- Transform vector
- "K nearest neighbors"
- Hash tables
- Divide vector space into regions
- Locality sensitive hashing
- Approximated nearest neighbors

Machine translation

Document search

Practice your skills in the assignment!
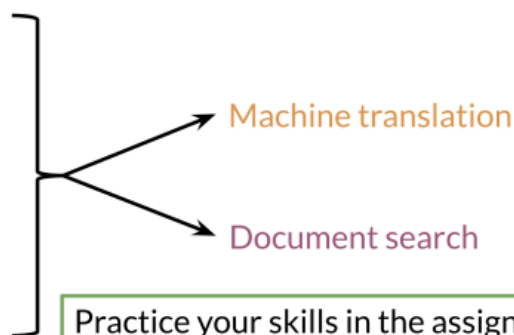

Good luck with the programming assignment!

You can use multiple planes to get a single hash value. Let's take a look at the following example:
$$\mathbf{P}_1\mathbf{v}^T = 3, sign_1 = +1, h_1 = 1$$

$$\mathbf{P}_2\mathbf{v}^T = 5, sign_2 = +1, h_2 = 1$$

$$\mathbf{P}_3\mathbf{v}^T = -2, sign_3 = -1, h_3 = 0$$

$$hash = 2^0 \times h_1 + 2^1 \times h_2 + 2^2 \times h_3$$
$$= 1 \times 1 + 2 \times 1 + 4 \times 0$$
$$= 3$$

Given some point denoted by **v,** you can run it through several projections P_1, P_2, P_3 to get one hash value. If you compute $P_1 v^T$ you get a positive number, so you set $h_1 = 1$. $P_2 v^T$ gives you a positive number so you get $h_2 = 1$. $P_3 v^T$ is a negative number so you set h_3 to be 0. You can then compute the hash value as follows.

$$hash = 2^0 \times h_1 + 2^1 \times h_2 + 2^2 \times h_3$$

$$= 1 \times 1 + 2 \times 1 + 4 \times 0 = 3$$

Another way to think of it, is at each time you are asking the plane to which side will you find the point (i.e. 1 or 0) until you find your point bounded by the surrounding planes. The hash value is then defined as:

$$hash_value = \sum_i^H 2^i \times h_i$$ $\longrightarrow$ (normvector$_i$). $v_i \geqslant 0$ then $h_i = +1$ else $h_i = -1$

Here is how you can code it up:

```python
def hash_multiple_plane(P_l,v):

    hash_value = 0

    for i, P in enumerate(P_l):
        sign = side_of_plane(P,v)
        hash_i = 1 if sign >=0 else 0
        hash_value += 2**i * hash_i

    return hash_value
```

P_l is the list of planes. You initialize the value to 0, and then you iterate over all the planes (P), and you keep track of the index. You get the sign by finding the sign of the dot product between v and your plane P. If it is positive you set it equal to 1, otherwise you set it equal to 0. You then add the score for the ith plane to the hash value by computing $2^i \times h_i$.
